No. 4

THE SPECIES OF PARONYCHIA (CARYOPHYLLACEAE) IN VICTORIA

by HELEN I. ASTON*

SUMMARY

Two species of Paronychia, P. brasiliana DC. and P. franciscana Eastwood, are naturalized in Victoria. Previous records of P. chilensis DC. are erroneous, and are due to misidentification of P. franciscana.†

METHOD

Except for one 1969 collection of P. brasiliana DC. from Genoa, East Gippsland, Willis (1973) referred all Victorian material of Paronychia to P. chilensis DC. Black (1963) also referred Victorian collections to P. chilensis but Eichler (1965) altered this determination to P. brasiliana.

To resolve the identity of the Victorian plants all Australian collections of Paronychia held by the National Herbarium of Victoria were examined. Two species were distinguished and, with the use of the revision by Chaudhri (1968), determined as P. brasiliana DC. and P. franciscana Eastwood. Portions of nine representative collections were submitted to Dr. M. N. Chaudri, University of Islamabad, Islamabad, Pakistan, who kindly confirmed the identifications.

DISTRIBUTION

Paronychia brasiliana DC.

The earliest Victorian collections held at Melbourne each bear a machine-printed, blue "Botanical Museum of Melbourne./Ferd. Mueller, Ph. & M.D." label annotated in unidentified handwriting with the locality of Melbourne Botanic Garden, but without collector or date. The collections were probably made before Mueller's death in 1896 and were possibly taken

^{*} National Herbarium of Victoria.

[†] Only one other species of *Paronychia* has been recorded from Australia. This is *P. argentea* Lam., which Black (1963) reported for South Australia from "Palmer (Murray lands west of river)". J. P. Jessop (pers. comm., Nov. 1976) could not locate any voucher collection for this report at the State Herbarium, Botanic Garden, Adelaide, and therefore Black's identification remains unverified.

from cultivated material. The only Victorian collections of undoubtedly naturalized populations are from East Gippsland (Genoa, 1969; Maramingo Hill, 1970; Buchan-Bruthen road, 1971; Mallacoota, 1972) and from the Melbourne suburb of South Yarra (1977). Several collections from eastern New South Wales are also held at Melbourne.

SPECIMENS EXAMINED:

(C) indicates verified by Dr. Chaudhri. Victoria—(C) Melbourne Botanic Garden, anon., ? pre-1896 (MEL 503801; MEL 503803); Shrine of Remembrance, South Yarra, Melbourne, in lawn, H. I. Aston 1998, 3.iii.1977 (AD, CANB; MEL 515990; NSW); Maramingo Hill, East Gippsland, A.C. Beauglehole 33629, 9.viii.1970 (MEL 516547); Buchan—Bruthen road, at junction of Dead Horse Creek Road, East Gippsland, A. C. Beauglehole 37551, 23.iii.1971 (MEL 516548); Shrine of Remembrance, South Yarra, Melbourne, in lawn, M. G. Corrick 5836 and 5837, 2.iii.1977 (MEL 515989; MEL 515991); (C) Genoa, grounds of Forests Commission's office, J. H. Willis and A. C. Beauglehole, 11.xi.1969 (MEL 504925); Mallacoota, camping and picnic reserve on north slopes of township, J. H. Willis, 19.xii.1972 (MEL 504924). New South Wales—(C) Sydney, W. V. Blewett, 27.iii.1931 (MEL 504923); Paterson, H. A. Fry, 28.iv.1933 (MEL 504926 (=NSW 51881)); Guyra, a common prostrate weed which has become widespread at Guyra, E. N. McKie 2450, summer 1945–46 (MEL 504928 (=NSW 51882)); Between Cambewarra Mountain and Beaumont, west of Nowra, J. H. Willis, 22.iii.1954 (MEL 504927).

This species is native to southern Brazil, Uruguay, and northeast Argentine and is introduced in South Africa and Australia. In Australia there are verified records from Victoria, New South Wales, the Australian Capital Territory, and south-east Queensland. (Beadle, 1972; Beadle, Evans and Carolin, 1972; Burbidge

and Gray, 1970; Chaudhri, 1968).

Paronychia franciscana Eastwood

The earliest collection held at Melbourne warrants exactly the same comment as that given for the earliest collections of *P. brasiliana*. Apart from this early collection of possibly cultivated material there are collections of undoubtedly naturalized populations from within the Melbourne suburban area (1909, 1946, 1961, 1965) and from the following widespread country locations in Victoria—Werribee River (1917) and Diggers Rest (1917), approximately 30 km south west to north west of Melbourne; Bairnsdale district (between 1917 and 1930); Eldorado (pre-1919) and Londrigan (1936), 20 km and 10 km respectively east of Wangaratta; Bendigo (1949); Rokewood/Shelford (1962), approximately 40 km south of Ballarat. There are no collections from other Australian States held at the National Herbarium of Victoria.

SPECIMENS EXAMINED:

(C) indicates verified by Dr. Chaudhri. Victoria—Melbourne Botanic Garden, anon., ? pre-1896 (MEL 503802); (C) Londrigan, R. A. Black, 16.xi.1936 (MEL 504934); (C) Werribee River, growing on banks, C. French jr., 15.i.1917 (MEL 504936); (C) Near Diggers Rest, common along road, C. French jr., 20.v.1917 (MEL 504930); Bairnsdale district, T. S. Hart, between 1917 and 1930 (MEL 504935); (C) Queens Park, Moonee Ponds, fairly plentiful, J. P. McLennan, 1909 (MEL 504931); Diamond Hill, Ben-

digo, F. Robbins, 29.x.1949 (MEL 516546); Shrine of Remembrance, Melbourne, lawns, R. V. Smith, ii.1946 (MEL); Shrine of Remembrance, lawns, R. V. Smith, 9.i.1961 (MEL); Eldorado, per H. B. Williamson, pre-1919 (MEL 504929); (C) At bridge on Warrambine Creek, between Rokewood and Shelford, J. H. Willis, 18.xi.1962 (MEL 504932); (C) South Yarra, J. H. Willis, 14.xii.1965 (MEL 504933).

P. franciscana is native to Chile and introduced in the vicinity of San Francisco, U.S.A., and in Australia (Victoria).

TAXONOMY

Chaudhri (1968) recognises 109 species of *Paronychia* Miller (1754). He places the three species considered here in the subgenus Paronychia (57 spp.), section Paronychia (56 spp.) and subsection Paronychia (39 spp.). Within this subsection Chaudhri maintains *P. brasiliana* DC. (1804) and *P. franciscana* Eastwood (1901) as distinct but similar species in the series Planitoriae (2 spp.) and places *P. chilensis* DC. (1828) in the series Paronychia (29 spp.). All three species are thus closely-related, and confusion between them is understandable.

P. brasiliana and P. franciscana share the following characters: -Plant perennial, herbaceous, with a slender woody tap root $1\cdot 0-2\cdot 0$ (-4\cdot 0) mm diameter. Stems to c. 30-35 cm long, to 1.5 mm diameter, much-branched, prostrate with ascending extremities, many-noded, the internodes < 2.0 cm long and often only 2-few mm, glabrous to pubescent; basal parts somewhat woody with the leaves fallen showing knotted nodes bearing persistent stipule-bases. Leaves 4-10 mm long, sessile, opposite or appearing whorled or fascicled, narrow-elliptic to ± oblanceolate, tapered to the base, acute, distinctly mucronate, moderately densely covered with forwardly-directed, simple hairs; mucro very slender, translucent, 0.3-0.9 (-1.0) mm long; leaf pair joined at the base on either side of the stem by a conspicuous, broad-lanceolate, acuminate, silvery-white, scarious stipule which splits longitudinally as growth proceeds, producing two half-stipules at the base of each leaf of the pair; leaves when fascicled each with two unsplit stipules at the base; stipules 2.5-6.5 mm long, with fine hairs along the margins. Flowers several together in pseudo-axillary clusters together with silvery, stipule-like bracts; clusters many along each stem, shorter than the subtending leaves. Flower near-sessile, with a cup-shaped receptacle (perigynous zone) 0.25-0.35 (-4) mm long, this receptacle much shorter than the sepals. Sepals 5, c. $1 \cdot 0 - 1 \cdot 4$ (-1.65) mm long (excluding awn), erect to slightly spreading, continuous with the summit of the receptacle, oblong, with a broad, thickened median band and a membranous margin, strongly concave with a distinct apical hood and a prominent, stiff, slender awn arising from the back of the hood. Petals absent or rarely appearing as a minute translucent projection c. 0.1 mm long arising from the summit of the receptacle at the junction of two sepals. Stamens 5, opposite to and attached at the base of the sepals, much shorter than the sepals; *filaments* filiform, c. $4\cdot 0$ mm long; *anthers* c. $1\cdot 5$ mm long, oblong, bilocular, dorsifixed, opening introrsely by longitudinal slits. Ovary superior, ovoid, inilocular with one ovule, minutely papillose particularly over the apical region; *style* very short and squat (almost absent) with two (rarely three) short, divergent, sometimes almost horizontal, stigmatic arms; *ovule* basal, amphitropous. *Fruit* an obovoid to subglobose utricle, c. $1\cdot 0-1\cdot 25$ mm long x $0\cdot 85-1\cdot 1$ mm broad, enclosed in the persistent calyx; pericarp membranous and rupturing at the base. *Seed* subglobose, smooth, dark.

The following key gives the distinctions between *P. brasiliana* and *P. franciscana* as shown by the Australian collections examined. These distinctions agree in essentials with those

given by Chaudhri (l.c.).

Flower clusters ± exposed, the leaves and stipules of each node usually shorter than the succeeding internode and therefore not concealing the flower cluster at the node above. Shoots with the nodal leaves and flower clusters moderately spaced along the stem, the internodes clearly visible. Flowers glabrous, or with a few short hairs externally at the junction of two adjacent sepals with the receptacle. Sepals equal, glabrous, deeply-hooded, at maturity the median band usually turning dark reddish-brown and the margin white and scarious; hood depth (distance from apex of hood to insertion of awn) c. 0·3–0·4 (-0·5) mm, the scarious margin occupying c. one third to one half of this depth. Awn 0·5–0·85 (-1·0) (average 0·6) mm long, spreading at an angle of 10°–80° (mostly c. 40°) from the longitudinal axis of the sepal, mostly about half (40%–62%, average 55%) as long as the sepal length (sepal base to point of attachment of the awn) . . . P. brasiliana Flower clusters mostly concealed by leaves and stipules, each

Flower clusters mostly concealed by leaves and stipules, each internode usually shorter than the leaves and stipules of the node below. Shoots usually densely covered with overlapping leaves and stipules, the internodes hidden. Flowers with short hairs externally at the junction of two adjacent sepals with the receptacle, and also usually hairy on the receptacle and the sepal hood, also often sparsely hairy over the whole sepal. Sepals somewhat unequal, 3 with very narrow margins and glabrous to slightly hairy, 2 with broad white scarious margins and usually strongly hairy, particularly on the hood, including the hood margin; all 5 sepals at maturity with the median band usually light straw-brown; hood depth c. 0.2-0.3 mm. Awn 0.4-0.6 (-0.7) (average 0.5) mm long, erect to spreading at an angle of 0° – 40° (mostly c. 10°), usually about one third (27%–45%, average 37%) as long as the sepal length ... P. franciscana . .

In brief, *P. franciscana* differs from *P. brasiliana* in the (usually) more densely-clothed shoots giving a more compact, mat-forming habit, the flowers pubescent rather than glabrous, the somewhat unequal, paler, less deeply-hooded sepals, and the shorter, erect or near-erect awns.

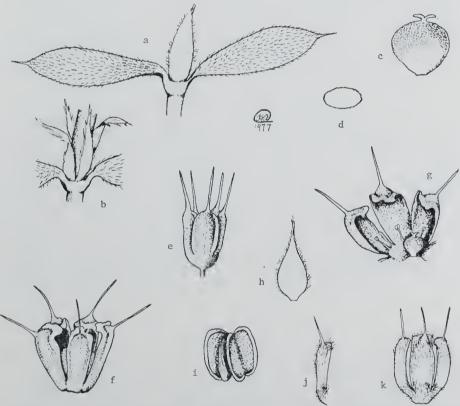

Fig. 1.—a-i, Paronychia brasiliana (from Aston 1998): a—leaf pair connected by stipule at base, x 6; b-base of leaf pair showing the stipule split lengthwise to produce two half-stipules per leaf, x 6; c-papillate ovary with style and stigmas, lateral view, x 14; d-ovary, T.S., x 4; e-flower bud, the awns still erect, x 11; f-mature flower, external view, showing the very small receptacle and the 5 glabrous sepals each with a thickened median band, membranous margin, deep hood, and slender, spreading awn, x 11; g-portion of mature flower from within, showing 3 sepals, gynoecium, short receptacle, and stamens, x 11; h-stipule x 10; i-anther after dehiscence, x 12. j-k, Paronychia franciscana (from Williamson, MEL 504929): j-one of the two broad-margined sepals, lateral view, x 11; k-portion of mature flower showing one broad-margined, strongly-hairy sepal and two narrow-margined, less hairy sepals. Note shallow hoods and short, erect awns, x 11.

Chaudhri (1.c.) also mentions very slight differences in internode pubescence and in styles, but these differences seem unstable. He gives larger stipules and very knotty shoots as further distinguishing characters for *P. franciscana*, but these

characters are not wholly reliable on the Australian material examined. However there is a tendency for larger stipules, shorter internode length, and a higher ratio of node diameter to internode diameter in some collections of *P. franciscana*. Coupling of the shorter internode and higher node/internode diameter ratio is more frequent in *P. franciscana*, and, where it occurs gives a more knotted appearance to the stem. This is most conspicuous over the lower stem portions from which leaves and stipules have fallen. Minimum, maximum and average measurements from the specimens seen are summarised as:—

P. brasiliana—stipule length 2.5-6.5 mm (average 4.4); internode length 1.5-19.0 mm (average 9.8); ratio node: internode diameter 1.8:1-2.5:1 (average 2.2:1).

P. franciscana—stipule length $4 \cdot 0 - 6 \cdot 0$ mm (average $4 \cdot 9$); internode length $2 \cdot 0 - 12 \cdot 0$ mm (average $5 \cdot 0$); ratio node: internode diameter $1 \cdot 6 \cdot 1 - 4 \cdot 0 \cdot 1$ (average $2 \cdot 3 \cdot 1$).

Until now, P. franciscana has been identified in Victoria incorrectly as P. chilensis, but this latter species is distinguished from both P. franciscana and P. brasiliana by the following characters:—

Receptacle well-developed, 0.8-1.0 mm long, only a little shorter than the sepal which is (excluding awn) 1.0-1.3 mm long; petals present, 0.25-0.3 mm long, subulate-filiform and indistinct; awn short, 0.25-0.3 mm. The first of these characters, the well-developed receptacle, is also the key distinction (Chaudhri, 1.c.) of the series Paronychia from the series Planitoriae (see opening paragraph under "taxonomy").

ACKNOWLEDGEMENT

Dr. M. N. Chaudhri's assistance with identification is gratefully acknowledged.

THE HERBACEOUS SPECIES OF ECHIUM (BORAGINACEAE) NATURALIZED IN AUSTRALIA

by C. M. Piggin *

SUMMARY

This field and herbarium study shows that there are three distinct herbaceous species of *Echium*, E. *italicum* L., E. *plantagineum* L. and E. *vulgare* L., naturalized in Australia. A key to these species, a description and distribution map for each, and lists of specimens in Australian herbaria are provided. An account of their overseas distribution, the history of their introduction and spread in Australia, and a discussion of previous nomenclatural confusion are also given.

INTRODUCTION

The genus *Echium* can be divided into two distinct evolutionary groups: the predominantly woody species of the Macaronesian Archipelago (about 25 species), and the herbaceous species which are native around the Mediterranean Sea and in the British Isles (about 25 species). The herbaceous species have been introduced and become quite widespread in southern Africa, the Americas, New Zealand and Australia.

In the past, the taxonomy and nomenclature of the genus have been confused in Australian and overseas literature. Following recent reviews of the European species by Gibbs (1971, 1972) an attempt is made here to clarify the nomenclature, taxonomy, history and distribution of the herbaceous *Echium* species naturalized in Australia.

MATERIALS

Field collections of *Echium* plants were made between 1969 and 1976 and specimens have been lodged at the Keith Turnbull Research Institute, Frankston, Victoria (KTRI), the National Herbarium, Sydney (NSW), the National Herbarium, Melbourne (MEL), the Melbourne University Herbarium (MELU), and the Royal Botanic Gardens, Kew, England (K). Other *Echium* specimens at the above Australian herbaria, and specimens at the Western Australian Herbarium, Perth (PERTH); the Northern Territory Herbarium, Alice Springs (NT); the State Herbarium of South Australia (AD) and the Waite Institute Herbarium (ADW), Adelaide; the Queensland Herbarium, Brisbane (BRI); Herbarium Australiense (CANB) and the Botanic

^{*} Keith Turnbull Research Institute, Department of Crown Lands and Survey, Frankston, Victoria, 3199.

Gardens Herbarium (CBG), Canberra; and the Tasmanian Her-

barium, Hobart (HO), were also examined.

All identifications were made by the author. Identities of representative specimens (those marked MEL*) were later confirmed by Dr. P. E. Gibbs, Department of Botany, The University, St. Andrews, Scotland.

KEY TO THE HERBACEOUS SPECIES NATURALIZED IN AUSTRALIA

1. Indumentum of coarse, stiff, crowded yellowish-white hairs; corolla yellowish-white, five stamens long-exserted E. italicum

1. Indumentum of softer, less-crowded white hairs; corolla blue, reddish, or purple, rarely white, stamens not all long-exserted

- 2. Indumentum of soft white hairs and sometimes, especially on the stems and leaf margins, a sparse underlayer of softer hairs; basal leaves broadly ovate, petiolate, with prominent lateral veins; two stamens long-exserted, one short-enclosed, and two intermediate-enclosed; corolla glabrous except for sparse hairs along veins and margins
- 2. Indumentum of sparse, stiff, tubercule-based white hairs and a dense underlayer of softer white hairs; basal leaves narrowly lanceolate, sessile, without prominent lateral veins; four stamens long-exserted, one short-enclosed; corolla pubescent, especially along veins and margins *E. vulgare*

DESCRIPTIONS

E. italicum L., Sp. Pl. 139 (1753)

Synonym: E. altissimum Jacq., Fl. Austriacae 5: 35 (1778) Common name: Italian Bugloss.

Erect, very hispid biennial or perennial, 40--100 cm tall, usually with a single, unbranched, spike-like flowering stem, but sometimes much branched; *indumentum* of coarse, stiff, crowded, yellowish-white setae (1–3 mm) and sometimes, especially on the stems and leaf margins, an underlayer of softer yellowish-white hairs. Basal *leaves* $200\text{--}350 \times 15\text{--}40 \text{ mm}$, lanceolate, the lateral veins quite apparent on lower surface; cauline leaves more or less narrowly elliptic. Calyx 6–7 mm; corolla 10–12 mm, very narrowly infundibuliform, yellowish-white, hairy—prominently so on veins and margins; 5 stamens long-exserted; filaments white-translucent; pollen yellowish; style hairy. Nutlets $2\cdot5 \times 3\cdot5 \text{ mm}$, triquetrous, irregularly tuberculate, whitish-grey.

Bugloss.

Erect, softly hairy annual or biennial, 20-60 (sometimes to 200) cm tall, with one to many flowering stems; indumentum of soft, appressed white setae (1-3 mm) and sometimes, especially on the stems and leaf margins, a sparse underlayer of softer white hairs. Basal leaves 50-200 x 15-100 mm, broadly ovate, petiolate, with prominent lateral veins on upper and lower surfaces; cauline leaves oblong to lanceolate, the uppermost more or less cordate at the base. Calyx 7-10 mm at anthesis, up to 15 mm in fruit; corolla 18-30 mm, broadly infundibuliform, blue becoming pink through purple, occasionally white, glabrous except for sparse hairs on the veins and margins; 2 stamens longexserted, 2 intermediate-enclosed, and 1 short-enclosed; filaments reddish-blue with occasional long hairs; pollen bluish-grey; style hairy. Nutlets 2 x 2.5 mm, triquetrous, tuberculate, pale brownish-grey.

E. vulgare L., Sp. Pl. 139 (1753)

Synonyms: E. asturicum Lacaita, Cavanillesia 1: (1928).

E. hispanicum Asso, Syn. Arag. Mant. 162 (1781).

E. lacaitae Sennen, Cavanillesia 2: 26 (1929) in obs.; and Bol. Soc. Iber. 29: 43 (1930).

E. lycopsis L., Fl. Anglica 12 (1754) pro parte (lectotype incl.).

E. pustulatum Sibth. & Sm., Fl. Graec. Prodr. 1: 125 (1806)

E. tuberculatum Gilib., Exerc. Phyt. 41 (1972) nom. illeg., non Hoffmanns & Link (1809).

E. vulgare subsp. asturicum (Lacaita) Klotz, Wiss. Zeitschr. Univ. Halle 11: 704 (1962).

E. vulgare var. pustulatum (Sibth. & Sm.) Rouy in Rouy, Foucaud & Camus, Fl. France 6: 113 (1900).

Common name: Viper's Bugloss.

Erect, hispid biennial, or sometimes annual, 20–100 cm tall, with one spike-like flowering stem or sometimes quite branched; indumentum of sparse, stout, appressed to patent, tuberculebased white setae (1-3 mm) and dense underlayer of soft, deflexed, appressed, white hairs. Basal and lower cauline leaves 50–150 x 10–20 mm, narrowly oblanceolate, attenuate to petiolate at the base, with no apparent lateral veins; upper cauline leaves narrowly elliptic to lanceolate, sessile. Calyx 5-7 mm; corolla 9-12 mm, infundibuliform, blue to bluish-violet, hairy—especially on the veins and margins; 4 stamens long-exserted and 1 shortenclosed; filaments reddish-blue; pollen bluish-grey; style hairy. Nutlets 1.5 x 2.5 mm, more or less triquetrous, rugose, brownish-grey.

According to Lacaita (1919) and Gibbs (1971, 1972),E. vulgare is a very variable species which requires detailed study throughout its area of distribution. Some authors (e.g. Willkomm & Lange, 1870; Boissier, 1879; Lacaita, 1919) have separated E. pustulatum Sibth. & Sm. as a distinct species. Australian material, however, quite constantly fits the description

given above.

SPECIMENS EXAMINED:

South Australia—Mt. Gambier, ex Department of Agriculture 253, 29.ii.1960 (ADW 21518); Millicent, ex Department of Agriculture 5962, 1.ii.1972 (ADW 40366); Clare, A. E. NOMENCLATURAL CONFUSION

In the past, there have been many mis-identifications of *Echium* material in the Australian herbaria and in the literature. These indicate that reports of all species, unless able to be verified, must be treated with caution. Major examples of misapplied names are given below:

- **E. creticum** L., Sp. Pl. 139 (1753): a separate species (Gibbs, 1971, 1972), although the name has been sometimes misapplied to material of *E. plantagineum* (Lacaita, 1919). Early reports of the occurrence of *E. creticum* in South Australia (see pp. 233–4) almost certainly refer to *E. plantagineum*.
- **E. italicum** L.: misapplied to two specimens of *E. plantagineum*, from South Australia (Oodnadatta, *Woskett*, 14.x.1955) and Western Australia (Denmark, *D. A. Herbert*, ii.1920). Such mis-identifications in Western Australia probably led Meadly (1956) and Blackall & Grieve (1965) to report incorrectly that *E. italicum* occurs in that state.
- **E. lycopsis** L., Flora Anglica 12 (1754), without description: this name has been used recently by some authors (e.g. Dandy, 1958; Eichler, 1965; Blackall & Grieve, 1965; Piggin, 1968; Burbidge & Gray, 1970; Chippendale, 1972; Churchill & de Corona, 1972; Willis, 1972; Parsons, 1973) for material of *E. plantagineum*. However, Gibbs (1971) has shown that the name was based indirectly on 1), plants which are not preserved as specimens but, from circumstantial evidence, probably were identical to plants later described as *E. plantagineum* L., and 2), a figure which fairly clearly resembles *E. vulgare*, particularly with respect to the corollas with four long-exserted stamens. The figure has been chosen as lectotype of *E. lycopsis* L. and, as it resembles *E. vulgare* rather than *E. plantagineum*, and because the publication of *E. vulgare* predates that of *E. lycopsis*, the name *E. lycopsis* cannot be used as the correct one for either *E. plantagineum* or *E. vulgare*.

In the Australian Herbaria, most specimens which were labelled *E. lycopsis* are *E. plantagineum*; however, one specimen of *E. vulgare* (between Bathurst and Oberon, *J. Thompson 1818*, 25.viii.1973) was mis-identified as *E. lycopsis*.

E. plantagineum L.: misapplied to several specimens of *E. vulgare* (Tarana, *C. Austin*, i.1941; Bathurst, *Brett*, xii.1914; Bathurst, *C. R. Brett*, xii.1916; Bell, *C. Burgess*, 29.xi.1958; Tumbarumba, *J. W. Cunningham*, ii.1910; Coxs River to Fish River and Sidmouth Valley, *J. H. Maiden & R. H. Cambage*, iv.1909; Nevertire, *E. K. Rutledge*, xii.1916; Buckland River, *H. B. Williamson*, xii.1918) and originally used for the first specimen of *E. italicum* collected in New South Wales (Shire of Coreen, near Corowa, *E. Bray*, 1914).

E. violaceum L.: this name was first published in the *Mantissa* (42:1767) but has since been discarded as a species name because it is a confusion of *E. rubrum* Jacq. and *E. rosulatum* Lange (Lacaita, 1919; Ewart & Tovey, 1920).

In Australia, early botanists commonly used the name E. violaceum for material of E. plantagineum. For example, plant descriptions and illustrations confirm that the E. violaceum referred to by Ewart and Tovey (1908, 1909) and Davey (1922) is E. plantagineum. The plant description, and a Mueller specimen labelled E. violaceum (Yarra, F. Mueller, date?), indicate that Bentham and Mueller's (1869) E. violaceum is E. plantagineum. The localities of Rutherglen and Gooramadda suggest that Adcock's (1914) E. violaceum is E. plantagineum. Many other authors (e.g. Maiden, 1905; Black, 1909; Carne, 1924; Audas and Morris, 1925; Black, 1926; Ewart, 1930; Anonymous, 1935; Gray, 1961) actually list E. violaceum as a synonym for E. plantagineum. Most herbarium specimens labelled E. violaceum are E. plantagineum (see pp. 231–232).

However, some collectors have misapplied the name *E. violaceum* to material of *E. vulgare* (Braidwood, *J. Cole*, 30.x.1945; Bathurst Experiment Farm, *Peacock*, x.1910; Hobart, *J. Rodway*, i.1916). The collection by Peacock suggests that his earlier report (Peacock, 1904) of *E. violaceum* occurring around Bathurst referred to *E. vulgare*; certainly, his indistinct illustration could easily be *E. vulgare*. The report by Maiden and Cambage (1909) of the occurrence of *E. violaceum* near Coxs River to Fish River and the Sidmouth Valley refers to *E. vulgare* because their specimen collected from there, strangely labelled *E. plantagineum* rather than *E. violaceum*, is in fact *E. vulgare*.

Similarly, Michael (1972) considered that the undescribed E. violaceum in William Macarthur's garden at Camden (Anonymous, 1843) was probably E. vulgare, presumably on the circumstantial evidence that E. vulgare is an earlier introduction than E. plantagineum (Michael, 1970). However, it might well have been E. plantagineum because the name E. violaceum was used most commonly for E. plantagineum, and E. plantagineum is quite common on the central coast of New South Wales, having been collected at Pennant Hills (1934), Castle Hill (1937), Bomaderry (1947), Terrigal (1948), Camden Park (1949), the Botanic Gardens, Sydney (1954), Doonside (1965), and Centennial Park, Sydney (1973). In contrast, E. vulgare is represented by only one collection in the area, from a cultivated plant in the Sydney Botanic Gardens (1938), although it is probably more common on the central coast region than this single collection suggests. It has been observed growing near the Eastwood Railway Station (P. W. Michael, pers. comm., August 1976).

E. vulgare L.: misapplied to several collections of E. plantagineum from South Australia (near Yudnapina, J. Z. Weber 76, 24.x.1966; Wantapilla Bore, J. Z. Weber 108, 26.x.1966; near Cook, P. Wilson 1700, 16.x.1960) and New South Wales (Black Mountain, P. McDonnell, 17.xii.1969). Several authors (Maiden, 1916; Moore, 1967; Macoboy, 1972) have also incorrectly applied the name E. vulgare to the abundant Echium in northeast Victoria and south-east New South Wales, which is in fact E. plantagineum. Similarly, early records of the occurrence of E. vulgare in South Australia almost certainly refer to E. plantagineum (see pp. 233–234).

OVERSEAS DISTRIBUTION

a) E. italicum

E. italicum occurs on dry, stony or sandy soils along roads, channels and sea shores, and in pastures throughout Europe (Gibbs, 1972); around the Mediterranean Sea in western Asia and northern Africa (Post, 1896; Blatter, 1919; Post, 1933; Hassib, 1951; Zohary, 1962; Quezel and Santa, 1963; Riedl, 1967); and throughout south-west Russia (Hegi, 1927; Flora URSS, 1953; Gibbs, 1972).

b) E. plantagineum

E. plantagineum has been reported as a plant of dry, sandy areas in England and the Channel Islands (Hill, 1760; Smith, 1823; Babington, 1839; Withering, 1845; Perring & Walters, 1962; Gibbs, 1972); throughout Europe (Gibbs, 1972); around the Mediterranean Sea in western Asia and northern Africa (Post, 1896; Tackholm, 1956; Quezel & Santa, 1963); on Madeira and the Canary Islands (Lems & Holzapfel, 1968); in South Africa (Thiselton-Dyer, 1904; Adamson & Salter, 1950; Guillarmod, 1971); in south-west Russia (Flora URSS, 1953; Gibbs, 1972); in the north-east United States (Gleason, 1963) and California (Abrams, 1951: Munz & Keck, 1959); in Uruguay and Argentina in South America (Lorentz, 1878; Roseveare, 1948); and in the North and South Islands of New Zealand (Cheeseman, 1906; Thomson, 1922; Hilgendorf, 1952). It was also found in Canada in Manitoba in 1953 (Scoggan, 1957).

c) E. vulgare

E. vulgare occurs on chalky, gravelly or sandy soils on roadsides, in waste places, and in pastures in England, Wales, southern Scotland, the Channel Islands, and eastern Ireland (Hill, 1760; Babington, 1839; Withering, 1845; Perring & Walters, 1962; Gibbs, 1972); throughout Europe (Gibbs, 1972); in South Africa (Phillips, 1951; Guillarmod, 1971); throughout Russia (Hegi, 1927; Flora URSS, 1953; Gibbs, 1972); in Canada, especially in the east (Macoun, 1884; Scoggan, 1950; Jones & Fuller, 1955; Baldwin, 1958; Gleason, 1963; Ferron & Cayouette, 1964; Frankton & Mulligan, 1970); throughout the United States of

America (Gray, 1842; Macoun, 1884; Norton, 1911; Pammel, 1911; Tidestrom, 1925; Steyermark, 1940; Jones & Fuller, 1955; Hitchcock, Cronquist, Ownbey & Thompson, 1959; Radford, Ahles & Bell, 1968; Correll & Johnston, 1970); in Chile in South America (Lopez & Olalquiaga, 1959; Correll & Johnston, 1970); and in the North and South Islands of New Zealand (Cheeseman, 1906; Thomson, 1922; Hilgendorf, 1952). It was reported to be naturalized in Japan at Hokkaido in 1969 (Osada, 1975).

INTRODUCTION, SPREAD AND DISTRIBUTION IN AUSTRALIA

The first introductions of *Echium* into Australia were probably in the 1800s when plants (seeds) were brought intentionally from the British Isles, the Mediterranean region, the Canary Islands, and the Cape region of South Africa (see Cocks, Boyce & Kloot, 1976) to various gardens in Victoria, New South Wales, South Australia and Tasmania. *E. italicum* was listed by Francis (1859) and Schomburgk (1871) as a

cultivated plant in the Adelaide Botanic Gardens.

E. plantagineum is probably the species referred to as E. violaceum in catalogues of plants growing in the Melbourne Botanic Gardens (Ginn, 1852—mis-spelt E. violacium; Mueller, 1858; Guilfoyle, 1883), the Macarthur garden, Camden (Anonymous, 1843), the Darling Nursery, Sydney (Shepherd, 1851), the Sydney Botanic Gardens (Botanic Garden Report, 1857) and the Adelaide Botanic Gardens (Francis, 1859; Schomburgk, 1871). It may also have been the species referred to as E. creticum from the Royal Society's Gardens, Hobart (Anonymous, 1867), although E. creticum and E. violaceum (? = E. plantagineum) were recognised as separate species in the Melbourne and Adelaide Botanic Gardens by Guilfoyle (1883) and Schomburgk (1871, 1872).

E. vulgare was listed as a cultivated species at the Sydney Botanic Gardens in 1828, and had been introduced from England in 1820 (Botanic Garden Report, 1828). It was probably also the species referred to as E. vulgare Brot.* from the Melbourne Botanic Gardens (Mueller, 1860) and as E. wierzbickii Haberle† from the Adelaide Botanic Gardens (Schomburgk,

1873).

Deliberate introduction and spread probably were encouraged by the availability of seed for purchase. For example, Heyne (1882), an Adelaide nurseryman, included E. croticum (no doubt, a mis-spelling of E. creticum, and possibly E. plantagin-

^{*} E. vulgare Brot.: Willkomm & Lange (1870) refer E. vulgare Brot. to E. pustulatum Sibth. & Sm. which, according to Gibbs (1971, 1972), is a synonym for E. vulgare L. However, Lacaita (1919) considered that E. vulgare Brot. is a synonym for E. tuberculatum Hoff. & Link which, according to Lacaita (1919) and Gibbs (1971, 1972), is a separate species.

[†] E. wierzbickii Haberle: a synonym or variety of E. vulgare L. according to Lacaita (1919), Bonnier (1926), and Coste (1937).

eum) and E. violaceum grandiflorum (probably E. plantagineum)

in his seed catalogue of flower plants.

Accidental introductions also occurred. Breakwell (1917, 1918) listed *Echium* as an impurity in canary and cummin seed imported into New South Wales from Morocco and France. Spread has also been encouraged by the movement of agricultural produce contaminated with *Echium* seed. *E. plantagineum* has been found in agricultural seed and fodder and in rat poisons made from crushed wheat in Western Australia (Anonymous, 1965; Peirce, 1970), in feed wheat coming into Tasmania (Anonymous, 1955), and in wastes from wool scouring plants in New South Wales (Anonymous, 1941).

a) E. italicum

E. italicum was first collected in New South Wales near Corowa in 1914. Since then, it has been found occasionally along the Corowa to Albury road and near Young (Anonymous,

Fig. 1.—Distribution of E. italicum in Australia (based on collection localities of herbarium specimens).

1924; Blakely, 1925; Anderson, 1939; McBarron, 1955; Department of Agriculture of New South Wales Report, 1961). Its rarity is probably due in part to the vigilance of noxious weeds officers in the shires where it occurs.

In South Australia, *E. italicum* was first collected at Caloote and Palmer Hill (Dec. 1909), Mt. Pleasant (April 1912), and Cudlee Creek (Dec. 1916). At Mt. Pleasant, it was considered an undesirable weed (Agricultural Bureau of South Australia Report: Mt. Pleasant, 1912). By 1926, it occurred in the Mt. Lofty Ranges and towards the Murray (Black, 1926). It has not spread greatly since then and now grows occasionally along the eastern scarp of the Mt. Lofty Ranges, mainly on stony, non-arable roadsides and waste areas (D. E. Symon, pers. comm., 1969).

In Western Australia, *E. italicum* has been reported by Meadly (1956) and Blackall & Grieve (1965) to occur sporadically in the south-west. However, these reports appear to have been based on mis-identified specimens of *E. plantagineum* at the Perth Herbarium, and *E. italicum* probably does not occur

in the State.

b) E. plantagineum

In Victoria reports of E. violaceum being naturalized by 1858 (Mueller, 1858; Bentham & Mueller, 1869) and beginning to spread, especially in the north-east around Walwa, the Shire of Towong, and Rutherglen, by the early 1900s (Ewart & Tovey, 1908, 1909; Ewart, 1913; Adcock, 1914; Davey, 1922) probably correctly refer to E. plantagineum. Certainly, early collections from Geelong (Dec. 1889), Apsley (1894), the Yarrawonga Shire (Oct. 1906), Corryong (Nov. 1906), the Towong Shire (Dec. 1906), Benalla (Aug. 1908), Kyneton (Dec. 1912), Cobram (Oct. 1915), and Durham, Shire of Gordon (Nov. 1921), mostly labelled E. violaceum, suggest that these early reports referred to E. plantagineum. The Cobram specimen had white flowers and aroused interest amongst members of the Royal Society of Victoria (Ewart, 1916). The spread of the species apparently caused concern because the plant was declared as a noxious weed, under the name E. violaceum, for the Shire of Towong in 1904, the Shire of Maldon in 1908, and the whole of Victoria in 1911. In 1921, it was re-proclaimed under the name E. plantagineum (Victorian Government Gazettes: February 1904, p. 509; 19 January 1908, p. 674; 15 February 1911, p. 1271; 18 May 1921, p. 1748). By the 1930s, it was common in the north-east and found to some extent in other localities (Ewart, 1930; Anonymous, 1935). It is now abundant in the north-east and common throughout the State on roadsides, waste areas, and pastures (Piggin, 1968; Churchill & de Corona, 1972; Willis, 1972; Parsons, 1973).

In New South Wales, E. plantagineum was reported, under the name E. violaceum, to be naturalized by 1859 (Hooker,

1859; Woolls, 1884, 1885; Anonymous, 1891; Moore & Betche, 1893). Soon after, specimens were collected from the Murrumbidgee (1875), Deniliquin (1897), Minore (Feb. 1899), between Tomah and Cockatoo, near Holbrook (Nov. 1900), Nyngan (Aug. 1903), Paldrumatta Bore (Oct. 1904), Dubbo (Oct. 1904), and Cumberoona (Nov. 1904), and all were labelled E. violaceum except the Murrumbidgee specimen which was labelled Echium. By 1905, it was spreading around Albury (Maiden, 1905) and the account of its dispersal from there is probably typical of what happened in many areas. Apparently, it was introduced as a garden flower at Cumberoona by a Mr. Paterson in about 1880. It remained as a small patch until about 1897, when it spread through a fence onto a travelling stock reserve and quickly became widespread on stock routes, reserves, paddocks throughout the district. By 1916, it had been reported from the Upper Murray, Bourke, Nyngan, Wilcannia, Dubbo, Hay and Jingellic (Maiden, 1905; Cambage, 1905; Agricultural Bureau of New South Wales, 1915; Maiden, 1916).

Fig. 2.—Distribution of E. plantagineum in Australia (based on collection localities of herbarium specimens).

McBarron (1967) gave a different account of the arrival of *E. plantagineum* in the Albury district, suggesting that it came with German settlers from South Australia after the Land Act of 1861 opened up large areas for selection. This suggestion is reasonable because the plant occurs in Germany, it is considered by Whittet (1968) to be a direct introduction into South Australia from Europe, and it is now widespread in South Australia.

The increasing occurrence of *E. plantagineum* in New South Wales between 1895 and 1934 is reflected in its increasing importance as a weed after it was proclaimed, under the name *E. violaceum*, in the first noxious weeds list of New South Wales, dated 10 July 1909 (Maiden, 1916):

	Date	Number of Shires and Municipalities proclaiming it a weed	Position in the 20 most important weeds of N.S.W.	Authority
1895		 0		Maiden 1915
May,	1914	 37	8	Maiden 1915
June,	1915	 42	7	Maiden 1915
May,	1917	 45	7	Maiden 1917 <i>a</i> , 1917 <i>b</i>
1919		 61	?	Maiden 1920
1934		 99	?	Anderson 1934

By the 1930s, E. plantagineum was widely naturalized in New South Wales (Goodacre, 1938; Carn, 1939; Anderson, 1939) and it is now abundant on the central and south-west slopes and adjacent plains (Department of Agriculture of New South Wales Report, 1961; Whittet, 1968; Willis, 1972), particularly around Albury (Godden, 1955; McBarron, 1955) and the Riverine Plain (Leigh & Mulham, 1965), Inverell and Armidale (Gray, 1961), the coastal and mountain regions around Sydney (Beadle, Evans & Carolin, 1962, 1972), and the Australian Capital Territory (Burbidge & Gray, 1970).

In South Australia, E. violaceum was reported to be natura-

In South Australia, *E. violaceum* was reported to be naturalized by 1889 (Schomburgk, 1889; Agricultural Bureau of South Australia Report: Gladstone, 1889). These reports, and others between 1895 and 1927 (Anonymous, 1906; Agricultural Bureau of South Australia Reports: Gladstone, 1895; Cherry Gardens, 1896; Lucindale, 1897; Northern Branches Conference, 1900; Stockport, 1901; Koolunga, 1904; Johnsburg, 1906; Cradock,

1907; Paskeville, 1907, 1908; Clare, 1910; Annual Congress, 1912; Port Germein, 1912; Spalding, 1914; Wirrabara, 1916; Conference of Upper-Northern Branches, 1918; Laura, 1919; Central Agricultural Bureau, 1927), describing the appearance and spread of Echium, E. vulgare, E. creticum, E. plantagineum, bugloss, blue weed, and salvation Jane, especially in the northern districts, probably all referred to E. plantagineum. Certainly, specimens collected from Blanchetown (1870), Georgetown (June 1893), the Flinders Range (Oct. 1901), Fullarton (Nov. 1903), Piles Paddock, near Adelaide (Oct. 1904, Oct. 1905), Gladstone (Dec. 1905, Sept. 1906, May 1907, Nov. 1913, Nov. 1920, Dec. 1923), Napperby (Sept. 1906), the Adelaide Plains (Nov. 1906), Hill River (Dec. 1906), between Port Lincoln and Coffins Bay (Jan. 1907), Beetaloo (Oct. 1908), Nuriootpa (Jan. 1912), Hammond (Sept. 1912), Moolooloo Station (Oct. 1915, Oct. 1918), Kapunda (Nov. 1916), Hawker (Oct. 1917), Caltowie (Oct. 1917), Barton (Sept. 1920), Mile End (Sept. 1923), Glen Osmond (Jan. 1924), and Petersburg (June 1924), and the report by Black (1909), suggest that only E. plantagineum was common in these areas during this period. By 1926, it grew in most settled districts (Black, 1926) and had, no doubt, spread largely as a result of man's agricultural activities. It was, with E. italicum, first proclaimed as a noxious weed for 10 councils in the south-east on 29 July 1943 (South Australian Government Gazette, 29 July 1943, p. 118; Orchard, 1948). Around this time, it was reported to be widespread and still increasing (Wood, 1937; Orchard, 1948; McAuliffe, 1953). Its ability to spread rapidly, establish, and persist on farming land was illustrated at Kybybolite Experiment Station where it was introduced between 1928 and 1933, was widespread over 60% of the Station by 1946, and had not been greatly reduced, despite vigorous control measures, by 1952 (McAuliffe, 1953). It now occurs from the northern semi-arid pastoral areas through the cereal lands to the high rainfall areas of the Adelaide Hills and the south east, and is still spreading (St. George-Grambauer & Rac, 1962; Department of Agriculture of South Australia, Leaflet No. 3987).

In Western Australia, the earliest collections of *E. plantagineum* were made from between Albany and the Swan River (Nov. 1881), the Darling Range (Nov. 1907), Guildford (Sept. 1916), and Darlington (Oct. 1925). The 1881 collection predates the generally believed story that Lady Campbell introduced it as a garden plant to Western Australia, at Broomehill, soon after 1900 during the construction of the Great Southern Railway. It spread rapidly along the railway and, by 1925, occurred extensively in paddocks around Broomehill, Kojunup, and Blackwood. It was sporadic further north and did not occur in the eastern districts (Carne, 1924; Carne & Gardner, 1925; Gardner, 1925, 1930, 1933). By 1956, it was

common throughout the south-west, from Northampton in the north to Esperance in the south (Meadly, 1956; Blackall & Grieve, 1965; Peirce, 1970). It now occurs in the great southern districts as a scattered roadside plant, and in pockets over large areas. In the higher rainfall areas, it is not widely-established. In the eastern, north-eastern, and northern wheatbelt areas, it follows the railway system with major occurrences centred on towns

(Pearce, 1972).

In Tasmania, *E. plantagineum* was reported, under the name *E. violaceum*, to be naturalized by 1869 (Bentham & Mueller, 1869; Spicer, 1878), and was first collected at South Arm (Dec. 1905) and Hobart (Dec. 1916). It was probably not widespread by 1912, when *E. vulgare* was proclaimed as a noxious weed, but had obviously increased by 1938 when the "*Echium* species" were proclaimed (D. I. Morris, pers. comm., 15 January 1971). In 1955, it was scattered in the north-east and around the Tamar Valley (Raphael, 1955) and, according to Curtis (1967), is now locally abundant on roadsides and more widespread than *E. vulgare*.

In Queensland, *E. plantagineum* was apparently first recorded at Yandilla in 1916 (White, 1934), although the earliest specimens at the Brisbane Herbarium were collected at Zillmere (Sept. 1920) and Freestone, near Warwick (Oct. 1921). By 1934 it was scattered, mainly in the south-east, and becoming significant as a weed (White, 1934). Everist (1957) reported that it was spreading slowly. It is now common on roadsides and in pastures in the south-east and has been collected as far north as Atherton (Sept. 1954, Oct. 1959) and as far west as Birdsville (Sept. 1966) and Offham (Oct. 1954), appearing mainly where contaminated seed is sown or fed to stock (Department of Agriculture of Queensland Report, 1963).

In the Northern Territory, E. plantagineum was first collected near Alice Springs (Oct. 1956). According to Chippendale (1972), it now grows in some cultivated areas and trucking yards around Alice Springs, but is barely naturalized. It has also been collected about 540 km to the north, in the garden

of Banka Banka Station (Aug. 1954).

E. plantagineum has been collected (Oct. 1939) on Norfolk Island, but probably is quite rare there.

c) E. vulgare

In Victoria, *E. vulgare* was first collected at Myrtleford (Nov. 1883), Boolarra (Mar. 1890), Korumburra (1893), and Towong (Mar. 1901). It was first proclaimed as a noxious weed in 1969, for the whole of Victoria (Victorian Government Gazette, 19 February 1969, p. 330). The plant is now scattered on roadsides and in pastures around Sorrento, Boneo Road, Tongala and Bright, and is abundant around Portland (Piggin, 1968; Churchill & de Corona, 1972; Willis, 1972; Parsons, 1973). Its occurrence around Portland and Sorrento suggests that it

may have arrived in ballast from early ships loading at these ports. Michael (1972) considered that *E. vulgare*, which often occurs around the older-settled areas of New South Wales, may have been an earlier introduction into Australia than *E. plantagineum*, which is more common in recently-settled areas.

The earliest collections of *E. vulgare* in New South Wales were by Maiden and Cambage at Coxs River to Fish River and Sidmouth Valley in April 1909; Cunningham at Tumbarumba in February 1910; Peacock and Brett at Bathurst in October 1910, December 1914, and December 1916; and Rutledge at Nevertire in December 1916. However, there was considerable confusion about the identity of these plants. The Maiden & Cambage specimen was labelled *E. plantagineum* on the herbarium sheet but reported (Maiden & Cambage, 1909) under the name *E. violaceum*. Peacock's specimen was labelled *E. violaceum*, suggesting that his earlier report of *E. violaceum* obtaining "a considerable footing" in the Bathhurst district (Peacock, 1904) referred to *E. vulgare*. Cunningham's 1910 specimen from

Fig. 3.—Distribution of E. vulgare in Australia (based on collection localities of herbarium specimens).

Tumbarumba and Brett's 1914 specimen from Bathurst were labelled E. plantagineum and the 1916 collections by Brett and Rutledge included one specimen labelled E. plantagineum and one labelled E. vulgare. These collections suggest that E. vulgare was quite common on the central and southern tablelands by the early 1900s. The plant was proclaimed as a noxious weed in December 1912 (Maiden, 1916). It probably did not occur around Albury in 1916, despite Maiden's (1916) rather confused report that "E. vulgare or plantagineum" was spreading in this area. Certainly, E. plantagineum is now abundant and E. vulgare does not occur in the Albury district, despite reports by Moore (1967) and Macoboy (1972) to the contrary (see p. 228). At present, E. vulgare is quite common on roadsides and, to a lesser extent, in pastures around the tablelands (Department of Agriculture of New South Wales Report, 1961; Willis, 1972), especially in the coastal and mountain regions near Sydney (Beadle et al., 1962, 1972) and in the Australian Capital Territory (Burbidge & Gray, 1970).

In South Australia, É. vulgare was first collected at Georgetown (1893), and this specimen is now lodged in the Melbourne Herbarium. The oldest specimen at the Adelaide herbaria is from Clare (Dec. 1943). As discussed earlier (pp. 233-4), reports around the 1900s of the occurrence and spread of E. vulgare in South Australia probably all refer to E. plantagineum. E. vulgare now grows sporadically only around Clare

and Mount Gambier (Eichler, 1965).

The earliest collections of *E. vúlgare* in Tasmania were from North Esk in 1881 and Port Arthur in 1892 (a rather indistinct fragment). It was later recorded at Cambridge (Feb. 1912) and Hobart (Jan. 1916), and was probably quite common at this time because it was proclaimed as a noxious weed in 1912. By 1955, it was scattered in the north-east and the Tamar Valley (Raphael, 1955) and is now an occasional plant in dry waste places (Curtis, 1967).

CONTRAST BETWEEN AUSTRALIA AND OVERSEAS

From information presented in this study and in Piggin (1976), it seems that the occurrence and abundance of the three *Echium* species considered here differs in their native regions from regions where they have become naturalized. In countries around the Mediterranean and Atlantic coasts of Europe and northern Africa, where they seem to be native, they are all common but rarely abundant on roadsides and in waste areas and pastures.

In countries where they are introduced the situation seems to be different. In southern Australia *E. plantagineum* is the most widespread species and is frequently abundant, *E. vulgare* is common but much less widespread and *E. italicum* is quite rare. A similar situation seems to exist with *E. plantagineum* and

E. vulgare in other places such as South Africa, north-west United States of America and southern South America which, like southern Australia, have Mediterranean-type climates. In contrast, in cooler places such as the British Isles, northern Europe, Russia, Canada and central and western U.S.A., E. vulgare is the most widespread and common species, although rarely is it as abundant as E. plantagineum in Australia, whilst E. italicum and E. plantagineum are less common. These contrasts are probably due to differences between regions or countries in the number and nature of early plant introductions, the suitability of climate, the extensiveness of agriculture, the human population density, and the occurrence of phytophagous organisms that attack each species (see Doing, 1966; Moore, 1967). Certainly, in Australia, E. plantagineum seems to be the species that was most commonly introduced as a garden plant around the 1850s, it is well suited ecologically to grow in the annual pasture areas of southern Australia (Piggin, 1976), and it is heavily attacked and damaged in Europe by a range of insects that do not occur in Australia (Wapshere, 1975).

ACKNOWLEDGEMENTS

The author is greatly appreciative of the advice and assistance given throughout this study by Ms. H. 1. Aston of the National Herbarium, Melbourne. Thanks are also due to officers of the Departments of Agriculture in South Australia, Tasmania, and Western Australia and the Department of Crown Lands and Survey in Victoria, and Dr. P. W. Michael of the University of Sydney, for assistance with field collections; Dr. P. E. Gibbs of Scotland for confirmation of plant identifications; Mr. P. M. Kloot of the Department of Agriculture and Fisheries in South Australia for comments on the manuscript; Directors and staff of the Australian herbaria for assistance with specimen examinations; and Mr. M. W. Wright for technical assistance.

A NEW SPECIES OF LASTREOPSIS (ASPIDIACEAE) FROM NORTH-EAST OUEENSLAND

DAVID L. JONES*

SYNOPSIS

Lastreopsis grayi is described as a new species from the rainforests of the Atherton Tableland in north-eastern Queensland. Its closest congener is another as yet undescribed Lastreopsis.

INTRODUCTION

Tindale (1957, 1961a, 1961b, 1965) has revised the genus Lastreopsis and discussed in detail the species which occur in Australia.

In August 1971 the author collected Lastreopsis species in the Tinaroo Hills on the Atherton Tableland of north-eastern Queensland. Among the specimens were several of a slender undescribed species with deeply dissected fronds and a solitary specimen of a similar but coarser species. Further specimens of both species were located in subsequent trips into the area during May 1972 and November 1974. The slender species will be described by Tindale in a forthcoming issue of Telopea. The coarser species is here described as new.

Lastreopsis grayi D. L. Jones, sp. nov.

Rhizoma erectum, 1·0-2·5 cm crassum, paleis sparse praeditum (plantis vetustioribus rhizomates secundaria axillares generantibus); paleae 1·0-2·5 mm longae, plerumque anguste lanceolatae badiaeque, ad marginem et basin rotundatam versus pallidiores, earum marginibus fimbriis expansis irregularibus sparse praeditis, apice obtuso vel attenuato; stipites 10-40 cm longi, circiter 3 mm lati, erecti, virides vel viridi-brunnei, nitidi, ad basin flexuosi, pilis parvis appressis sparse ornati (praesertim in canaliculo), ad basin paleis sparsis similibus illis in rhizomati; rhachides patenter alatae, virides vel viridi-brunneae, leves, in canaliculo a pilis parvis ornatae; lamina anguste triangularis, 15-40 cm longa, 10-35 cm lata, tripinnatifide vel quadripinnate dissecta, pallide vel saturate viridis, glabra, nitens; pinnae primariae infimae maximaeque 8-16 cm longae, 3-10 cm latae, ad rhachidem primam oblique inclinantes, basiscopice dilatatae, apice attenuato dentatoserratoque; pinnae secondariae ad rhachidem secundariam obliquae, illia hacalibus argusta aletia illia guarairibus letta aletia adretia ad illis basalibus anguste alatis, illis superioribus late alatis adnatisque, apice attenuato dentato-serratoque; segmenta ultima pedicellis alatis apice attenuato dentato-serratoque; segmenta ultima pedicellis alatis praedita, alternantia, oblonga, aliquando falcata, non congesta, apice obtuso, subter glabra vel a glandibus flavis ornata; venae in superficie submersae et non prominentes, infra clariores liberae simplices vel unifurcatae; costae et costulae glabrae vel a pilis parvis atque glandibus flavis sparse vestitae; venulae similes; sori exindusiati, orbiculares, 0·5-1·0 mm lati, marginales (in parte interiore loborum), ad apicem venularum gesti, juveniliter albi, mature ferruginei vel fuscobrunnei; sporangia 90-140 per sorum, eorum annulo c.12-15 cellulas induratas et 6-10 cellulas tenues comprehendenti pedicello c.5-cellulas induratas et 6-10 cellulas induratas et 6-10 cellulas tenues comprehendenti pedicello c.5-cellulas induratas et 6-10 cellulas tenues comprehendenti pedicello c.5-cellulas induratas et 6-10 cellulas tenues comprehendenti pedicello c.5-cellulas induratas et 6-10 cellulas induratas et 6-10 cellulas tenues comprehendenti pedicello c.5-cellulas induratas et 6-10 cellulas induratas et 6-10 cellulas tenues comprehendenti pedicello c.5-cellulas et 6-10 cellulas et 6-10 cellulas et 6-10 c induratas et 6-10 cellulas tenues comprehendenti, pedicello c.5-cellulari pilum stipitatum oblongum aurantiacum glandulosumque gerenti; sporae bilaterales, globoso-ellipsoidales, fulvae.

^{*} Horticultural Research Institute, Knoxfield, Victoria

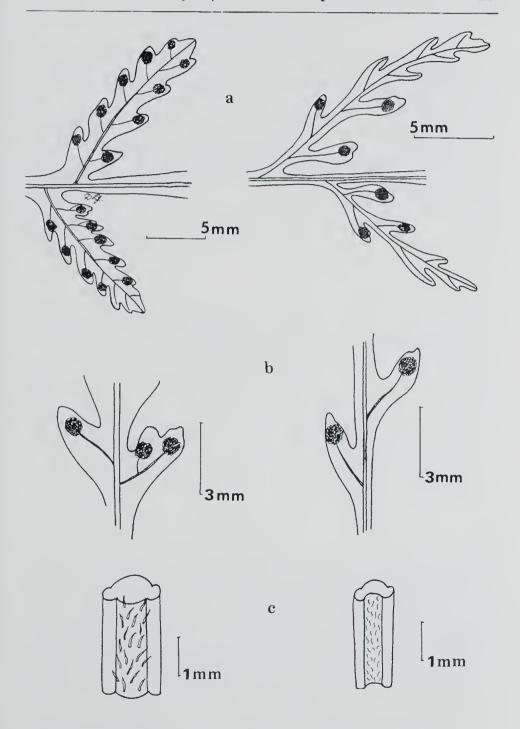

HOLOTYPE: Queensland, Cook District; rainforest along small creek in Lamb Range (Tinaroo Hills), 2 kilometres south-west of Mt. Haig, Atherton Tableland, at about 1000 m altitude. (17°06′S; 145°34′E.), D. L. Jones, B. Gray & R. Collins, xi. 1974 (BRI).

ISOTYPES: BRI, NSW, MEL.

Rhizome erect, 1-2.5 cm broad, in older plants producing secondary axillary rhizomes and becoming multi-crowned, sparsely clothed with scales; scales 1-2.5 mm long, some ovate and pale but most dark brown, narrow-lanceolate, paler towards the rounded base and the margin, the margins sparsely clothed with irregular spreading fimbriae, the apex obtuse or drawn out: stipes 10-40 cm long and about 3 mm wide, erect, green or greenish-brown, shiny, flexuose at the base, clothed sparsely with small appressed hairs especially in the groove, the scales of the base sparse and similar to those on the rhizome; minor rhachises conspicuously winged, green or greenish-brown, smooth, clothed with small hairs in the channel; lamina narrow triangular in outline, 15-40 cm long x 10-35 cm wide, 3-pinnatifid or 4-pinnate, anadromous, dissected and lacy, pale or dark green, shiny, glabrous; lowest primary pinnae the largest, 8-16 cm long and 3-10 cm wide, obliquely set to the main rhachis, basiscopically enlarged, the apex attenuated and dentate/serrate; secondary pinnae oblique to the secondary rhachis, the basal ones narrowly winged, the upper ones broadly winged and adnate, the apex attenuate and dentate/serrate; ultimate segments with winged pedicels, alternate, oblong, occasionally falcate, not crowded, the apex obtuse, undersurface glabrous or with small yellow glands; veins on the upper surface submerged and not prominent, those on the lower surface more prominent, free, simple or once forked; costae and costules glabrous or sparsely clothed with small hairs and yellow glands; veinlets similar; sori 0.5-1 mm in diameter, exindusiate, rounded, borne at the apex of veinlets, marginal, on the inner side of lobes, white when young, rusty brown or dark brown when mature; sporangia 90-140 per sorus; annulus composed of about 12 to 15 indurated cells and 6-10 thin walled cells; pedicel of about 5 cells, often bearing a stalked oblong, orange glandular hair; spores bilateral, monolete, globose-ellipsoid, yellow-brown; perispore crested, with balloon-like wings.

DISTRIBUTION AND ECOLOGY

Lastreopsis grayi is only known from scattered localities in the Tinaroo Hills of north-eastern Queensland. It always occurs in dense rainforest, usually along small creeks and gullies, growing both in the soil and leaf litter of the rainforest floor as well as on rocks. Plants are often solitary or in small scattered colonies.

Lastreopsis grayi

Lastreopsis sp.

Fig. 1.—a—Part of secondary rhachis and ultimate segments; b—Lobes of ultimate segments with sori; c—Section of rhachis.

DISCUSSION

Lastreopsis grayi is a rare species, the closest congener of which is another undescribed Lastreopsis. This latter species is more common and widespread than L. grayi, usually grows in fairly large colonies and is easily recognised by the very fine, lacy, deeply dissected fronds. The differences between the two are shown in Table I and some comparisons are made in the accompanying figure. Both species are readily distinguished from other native Lastreopsis with erect tufted rhizomes by the finely dissected, lacy fronds, the blunt segments lacking spines, and the exindusiate sori.

Lastreopsis sp.	Lastreopsis grayi
stipes shallowly grooved, the hairs about 0·1 mm long	stipes deeply grooved or ridged, the hairs about $0.3-0.5$ mm long
secondary rhachises inconspicuously winged	secondary rhachises conspicuously winged
ultimate segments deeply lobed, the lobes long and widely spaced	ultimate segments shallowly lobed, the lobes short and closely spaced
sori one per lobe, each sorus of up to 50 sporangia	sori 1–4 per lobe, each sorus of up to 140 sporangia

Table 1.—Contrasting characters.

The rarity of *L. grayi* prompted speculation that the species was a hybrid. A thorough study of two colonies during November 1974 showed nothing to support this hypothesis. Significantly, there were no species in the localities with the characters necessary to create the progeny. The only other *Lastreopsis* nearby were *L. rufescens* (B1.) Ching and *L. wurunuran* (Domin) Tindale, both villous, coarse-leaved species. It was interesting to note that there were many sporelings of *L. grayi* present in one colony and these were readily recognisable as the species. Sporelings have been raised by the author and have come true to type.

The epithet grayi is a tribute to Mr. Bruce Gray of Atherton. He is a very observant collector with a unique knowledge of north Queensland flora, and has many interesting botanical

discoveries to his credit.

ACKNOWLEDGEMENTS

The author wishes to express thanks to Mr. B. Gray for hospitality, specimens and information, Mr. S. B. Andrews, Botanist, Queensland Herbarium, for encouragement and criticism of the manuscript and Dr. J. H. Willis for preparation of the Latin description.

A NEW COMBINATION IN PULTENAEA JUNIPERINA Labill. (PAPILIONACEAE)

by

MARGARET G. CORRICK*

Pultenaea juniperina Labill. in Nov. Holl. Plant. Specim. 1:102, t.130 (1806) var. mucronata (Bentham) M. G. Corrick, comb. nov.

Pultenaea flexilis Sm. in Ann. Bot. 1:502 (1805) var. mucronata Bentham in Fl. austr. 2:135 (1864).

Pultenaea juniperina Labill. var. planifolia H.B. Williamson

in Proc. Roy. Soc. Vict. new ser. 33:138 (1921).

The holotype of Pultenaea flexilis var. mucronata Benth. is a "Clarence river, Beckler" collection, of which material is held at the Royal Botanic Gardens, Kew (K-photograph seen) and National Herbarium of Victoria (MEL 515976). P. juniperina var. planifolia Williamson is based partly on the same Clarence River collection and the name is therefore illegitimate and must be rejected (Article 63, International Code of Botanical Nomenclature). Williamson's placement of the variety under P. juniperina rather than under P. flexilis is botanically correct and the new combination of P. juniperina var. mucronata is therefore necessary.

ACKNOWLEDGEMENT

I wish to thank Miss Helen Aston of the National Herbarium of Victoria for assistance and advice.

PLACYNTHIUM (Ach.) S. F. Gray, A GENUS OF LICHENS PREVIOUSLY UNREPORTED FROM AUSTRALIA

by William A. Weber*

During my tenure of a fellowship from the Australian National University, 1967-1968, I had the opportunity of collecting lichens intensively in New South Wales. From these collections I report the following two species of *Placynthium* (Ach.) S. F. Gray, a genus for which there are no previous records from Australia (Weber & Wetmore 1972).

Placynthium nigrum (Huds.) S. Gray. New South Wales—5 miles east of Cooma on road to Numeralla, on limestone outcrop above the stream, Weber & McVean L-49054, 2.x.1967 (COLO); head of Neringla Creek, 3 miles NE of The Big Hole near Krawaree, east of the Shoalhaven River, on limestone in wet sclerophyll forest, 2500 ft alt., Weber & McVean L-49723, 19.iii.1968 (COLO). This species is characterized by having squamulose lobes and usually a prominent, bluish-black prothallus. A common and widely distributed species in Europe and North America.

Placynthium subradiatum (Nyl.) Arn. New South Wales—Bungonia Lookdown, on rimrock above Shoalhaven River Gorge, on massive limestone boulders, Weber & McVean L-48907, 10.iv.1968 (COLO, CANB, MEL). This species has a thallus with radiating, contiguous marginal lobes; characteristically the interior portions of the thallus flake off in age leaving arcs of tissue formed by the leading edges. A species widely distributed in Europe and North America (Henssen 1963).
